## SYNTHESES

The Mannich base was synthesized following the procedure published by Fenton et al. ${ }^{1}$ The typical procedure for the synthesis of ligands and the corresponding complexes is illustrated below.

## Synthesis of the chiral Mannich Base $\boldsymbol{R}$-/S- (Scheme S1)

$(R)-(+)-N, \alpha$-Dimethylbenzylamine $(0.5680 \mathrm{~g}, 4.2 \mathrm{mmoles})$, paraformaldehyde ( $0.2180 \mathrm{~g}, 7.2$ mmoles) and 5-bromosalicylaldehyde ( $1 \mathrm{~g}, 4.97$ mmoles) were refluxed in 50 mL methanol for five days. The yellow solution was cooled and the solvent was evaporated under reduced pressure, affording a yellow sticky oil. The chiral Mannich base was purified on a $\mathrm{SiO}_{2}$ chromatography column. The unreacted 5-bromosalicylaldehyde was eliminated using dicholoromethane, while the main product was eluated with ethyl acetate $[0.8090 \mathrm{~g}$; . yield: $47 \%$
(R); 0.5320 g; yield: $31 \%(S)$ ]. FTIR ( $\mathrm{cm}^{-1}$ ): 2975 (w), 1596 (w), 1450 ( s$), 1364$ (vs), 1223 (m), $1135(\mathrm{~m}), 1029(\mathrm{~m}), 862(\mathrm{~m}), 738(\mathrm{~m}), 701(\mathrm{~s}), 667(\mathrm{w}), 542(\mathrm{~m}), 454(\mathrm{~m})$.

Scheme S1. Synthesis of the chiral Mannich base.

## Synthesis of the chiral nitronyl-nitroxide $\boldsymbol{R}$-/S-HL ${ }^{4}$ (Scheme S2)

To a methanolic solution ( 40 mL ) of [2,3-bis(hydroxyamino)-2,3-dimethylbutane] $\cdot \mathrm{H}_{2} \mathrm{SO}_{4}(0$. $0.3925 \mathrm{~g}, 1.59 \mathrm{mmoles}$ ), which was deprotonated with $0.7 \mathrm{~mL} \mathrm{Et}_{3} \mathrm{~N}$, the $(R-/ S-)$ Mannich base ( 0 . $0.5546 \mathrm{~g}, 1.59$ mmoles) was added under stirring at room temperature. The resulting mixture was stirred at room temperature for four days, then concentrated under reduced pressure giving the reaction product as a pale-yellow oil which was solubilized in 50 ml dichloromethane. To the resulted solution solid $\mathrm{KIO}_{4}$ was added, then 20 mL water. The mixture was vigorously stirred for one hour at $0^{\circ} \mathrm{C}$, then dried over anhydrous $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure to obtain a purple oil. The stable nitronyl nitroxide radical was purified on a chromatography column $\left(\mathrm{SiO}_{2}\right)$ using diethyl ether as eluent. The organic solution was dried over anhydrous magnesium sulfate and concentrated under reduced pressure to obtain a purple solid [0.2460 g, yield: 46 \% ( $R$ ); 0.3180 g yield: $59 \%(S)$ ]. FTIR KBr pellet ( $\mathrm{cm}^{-1}$ ): 3402 (w), 2962 (w), 2934 (w), 1656 (m), 1594 (w), 1453 (vs), 1403 (s), 1367 (vs), 1336 (s), 1297 (m), 1259 (m), 1207 (s), 1164 (s), 1136 (w), 1092 (w), 1053 (w), 864 (w), 756 (m), 703 (m), 663 (w), 543 (w), 455 (w).

Scheme S2. Synthesis of the chiral nitronyl-nitroxide ligands.
Synthesis of [CoDy(hfac) $\left.\mathbf{5}_{\mathbf{5}}\left(\boldsymbol{R}-\mathbf{H L}^{4}\right)\right]$. To 20 mL hot $n$-heptane solution of $\left[\mathrm{Co}(\mathrm{hfac})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ $(0.016 \mathrm{~g}, 0.031 \mathrm{mmol})$ and $\left[\mathrm{Dy}(\mathrm{hfac})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right](0.026 \mathrm{~g}, 0.031 \mathrm{mmol})$, a chloroform solution (2 $\mathrm{mL})$ of $R-\mathrm{HL}^{4}(0.015 \mathrm{~g}, 0.031 \mathrm{mmol})$ was added and the mixture was stirred for one minute. The resulting solution was cooled down to room temperature and purple crystals were obtained after few hours. FTIR (cm ${ }^{-1}$ ): 1643 (m), 1531 (m), 1503 (m), 1453 (m), 1345 (w), 1252 ( s$), 1195$ (s), 1139 (vs), 1096 (s), 950 (w), 797 (m), 660 (s), 585 (m), 527 (w), 457 (w), 417 (w).

Synthesis of the nitronyl-nitroxide from 5-bromosalicylaldehyde, $\boldsymbol{H} \boldsymbol{L}$. The synthesis of HL radical have been performed in similar way as for $R-/ S$ - $\mathrm{HL}^{4}$ nitroxides, using 2 moles of [2,3-bis(hydroxyamino)-2,3-dimethylbutane] $\cdot \mathrm{H}_{2} \mathrm{SO}_{4}$ and 5-bromosalicylaldehyde, ( 0.260 g , yield: 40 \%).

Synthesis of $\left(\mathbf{H N E t}_{3}\right)$ [DyL(hfac) $)_{3}$ ] 12. To 20 mL hot $n$-heptane solution of $\left[\mathrm{Dy}(\mathrm{hfac})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right.$ ] $(0.026 \mathrm{~g}, 0.03 \mathrm{mmol})$, a chloroform solution ( 2 mL ) of HL ( $0.010 \mathrm{~g}, 0.03 \mathrm{mmol}$ ) containing two drops of triethylamine, was added and the mixture was stirred for one minute. The resulting solution was cooled down to room temperature and blue-purple crystals were obtained after three days, ( 0.028 g , yield: $77 \%$ ).

Synthesis of $\left(\mathbf{H N E t}_{\mathbf{3}}\right)_{\mathbf{2}}\left[\mathbf{C o L}(\mathbf{h f a c})_{\mathbf{2}}\right]\left[\mathbf{T b}(\text { hfac })_{4}\right]$ 13. To 20 mL hot $n$-heptane solution of $\left[\mathrm{Co}(\mathrm{hfac})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right](0.016 \mathrm{~g}, 0.03 \mathrm{mmol})$ and $\left[\mathrm{Tb}(\mathrm{hfac})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right](0.026 \mathrm{~g}, 0.03 \mathrm{mmol})$, a chloroform solution ( 2 mL ) of $\mathrm{HL}(0.010 \mathrm{~g}, 0.03 \mathrm{mmol})$ containing two drops of triethylamine, was added and the mixture was stirred for one minute. The solution was then allowed to cool to room temperature. After three days a blue-purple crystals were obtained, ( 0.030 g , yield: $58 \%$ ).

## Physical Measurements.

IR spectra ( KBr pellets) were recorded on a Tensor 37 spectrophotometer in the $4000-400 \mathrm{~cm}^{-1}$ region. Diffused reflectance circular dichroism (DRCD) spectra of crystalline samples were performed on a JASCO J-1500 spectrophotometer equipped with an integrating sphere attachment (DRCD-575 accessory) in the 200-800 nm domain at a scan rate of $100 \mathrm{~nm} / \mathrm{min}$ and accumulated twelve times. DC magnetic measurements were carried out using a Quantum

Design MPMS SQUID magnetometer. All compounds were wrapped in polytetrafluoroethylene (PTFE) tape and pressed into a pellet before measurement. Magnetic data were corrected for the sample holder and diamagnetic contributions for all magnetic measurements. AC magnetic measurements were performed on a Quantum Design PPMS using the ACMS option. Powder XRay Diffraction patterns have been recorded with a Bruker D8 Advance diffractometer ( $\mathrm{CuK} \alpha$ radiation).

## Crystallographic Data Collection and Structure Determination.

X-ray diffraction measurements were performed on a STOE IPDS II and on a Bruker D8 Venture diffractometers operating with a $\mathrm{Mo} \mathrm{K} \alpha(\lambda=0.71073 \AA$ ) X-ray tube with graphite X monochromator The structures were solved (SHELXS-2014) by direct methods and refined (SHELXL-2014)by full matrix least-squares procedures on $F^{2} .^{2}$ All non-H atoms of the donor molecules were refined anisotropically, and hydrogen atoms were introduced at calculated positions (riding model), included in structure factor calculations, but not refined. Due to large conformational disorder and to thermal motion present in CF3, large thermal displacement parameters were found for disordered fluorine atoms. Crystals of compound $\mathbf{1 3}$ have poor quality and are weakly diffracting. Crystallographic data for the structures have been deposited in the Cambridge Crystallographic Data Centre, deposition numbers CCDC 1922779-1922792. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data request/cif

Table S1. Crystallographic data, details of data collection and structure refinement parameters for compounds 1-13.

Calculations on compounds 5 and $\mathbf{8}$ were performed with MOLCAS 8.0 quantum chemistry software. ${ }^{5}$ For all compounds the geometries resolved by x-ray diffraction were employed. For both compounds calculations were performed on both crystallographic independent molecular units ( $\mathbf{A}$ and $\mathbf{B}$ ) inside the unit cell. In order to reduce the number of primitive functions due to computational limitations, some structural approximations were adopted: i) the x-ray structures were employed replacing $-\mathrm{CF}_{3}$ groups with $\mathrm{CH}_{3}$ groups ii) the methyl groups of the NNit moiety were replaced by hydrogens atoms iii) the chiral moiety and the methyl group bonded to the tertiary amine were replaced by hydrogens atoms. The effects on the electronic structure due to the first and the second structural modifications were evaluated in our previous publication, ${ }^{6}$ while the third one is also expected not to strongly influence the magnetic properties of the complex due to the distance of the chiral group from the magnetic centers. No further optimization was carried on.

The energy ladder of the electronic states for the dimeric Dy (III) and Co (III) ions obtained by doping the NNit with an extra electron in order to turn it into a diamagnetic ligand have been computed within the CASSCF/CASSI-SO method. The single ion anisotropies of the two metal ions have also been computed on the individual center by diamagnetic substitution on the other
two magnetic centers keeping the radical doped: $\mathrm{Zn}(\mathrm{II})$ and $\mathrm{La}(\mathrm{III})$ for $\mathrm{Co}(\mathrm{II})$ and $\mathrm{Dy}(\mathrm{III})$, respectively. The chosen active space for $\operatorname{Dy}($ III ) consists of nine electrons in the seven $4 \mathrm{f}-$ orbitals of the lanthanide ion: CAS $(9,7)$. Due to hardware limitations, only the 21 sextuplets were computed and included in the following spin-orbit calculation. The chosen active space for $\operatorname{Co}(\mathrm{II})$ consists of seven electrons in the seven 3d-orbitals of the metal ion: CAS $(7,5)$. The ten quadruplets and the forty doublets were computed and included in the following spin-orbit calculation. No perturbative method in order to recover part of the dynamical correlation was performed, due to memory limitation.

The g-tensors were computed with the SINGLE_ANISO module. ${ }^{7}$ Both metal ions are Kramers' ion due to their odd number of electrons. Their magnetic anisotropy was investigated within the pseudospin framework and their anisotropy axes were calculated with a pseudospin $S=1 / 2$.

To compute the isotropic magnetic coupling between the radical and the metal ions, CASSCF calculations were performed without spin-orbit contribution for the two compounds. In compound 5, the exchange couplings between the metal ions and the radical were computed singly substituting them in turn by their diamagnetic equivalent ( Dy (III) and Co (II) ion or doped state (Rad) (see above). For the Dy(III)-NNit interactions in $\mathbf{5}$ and $\mathbf{8}$, the chosen active space consisted of nine electrons in the seven 4f-orbitals of the lanthanide ion and the unpaired electron in the $\pi^{*}$ orbital of the $\mathrm{O}(1)-\mathrm{N}(1)-\mathrm{C}-\mathrm{N}(2)-\mathrm{O}(2)$ system on the radical, CAS $(10,8)$. For the cobaltradical interaction in DyCoNNit, the active space consisted of the five 3d orbitals and the $\pi^{*}$ molecular orbital of the Rad, CAS $(8,6)$. Finally, in order to compute the Co-Dy interaction, the GASSCF approach was employed: the radical was not doped but its $\pi^{*}$ orbitals was considered inactive. Only a maximum of two excitations, $\operatorname{GASSCF}(2)$, were allowed from the seven 4 f orbitals of the lanthanides to the five 3d orbitals of the Cobalt for computational hardware limitation. Regarding the Dy-rad and Co-rad interactions, calculations were performed converging on both the ferromagnetic and antiferromagnetic states resulting from the coupling of the unpaired electron localized on the radical and the unpaired electrons on the Dysprosium and Cobalt ions: the lowest septuplet and quintuplet states for the interaction Dy-rad; the lowest quintuplet and triplet states for the Co-rad. Regarding the Co-Dy interaction, by means of the previously described GASSCF approach, GASSCF(2), it was possible to converge to the lowest decuplet and octuplet states in energy.

The values of the exchange coupling constants were computed within the Heisenberg model, therefore using the real $S$ values of each magnetic species involved, i.e. $1 / 2,3 / 2,5 / 2$, for Rad, $\mathrm{Co}(\mathrm{III})$, and Dy (III), respectively:

$$
J_{H e i s}=\frac{-\left(E_{H S}-E_{L S}\right)}{S_{H S}}
$$

$\mathrm{E}_{\mathrm{HS}}$ and $\mathrm{E}_{\mathrm{LS}}$ are the energy of the High Spin (ferro) and Low Spin (antiferro) configurations, respectively, and $\mathrm{S}_{\mathrm{HS}}$ is the spin quantum number of the HS configuration.

The $\chi \mathrm{T}$ curves were simulated by means of the POLY_ANISO software with the Lines' model. In the Lines model the Heisenberg isotropic exchange interaction is firstly computed between isotropic spin multiplets ( $\mathrm{S}=5 / 2$ for Dy and $\mathrm{S}=3 / 2$ for Co ) and then projected on the basis of the previously computed spin-orbit states. In our models, for compound $\mathbf{8}$ only the exchange coupling interaction between the lanthanide and the coordinated isotropic $S=1 / 2$ of the radical was considered, while for compound 5 all the three exchange coupling interactions between the lanthanide, the cobalt ion, and the radical were considered, since none of the three can be neglected as suggested by ab initio calculations. The exchange interactions have been computed considering only the six lowest states in energy of the lanthanide ion, the four lowest ones of the Cobalt ion and the isotropic doublet of the radical. In order to reproduce the high temperature data also the single ion crystal field splitting for the two metal ions was included in the model. In this Hamiltonian, the only parameter present is the exchange coupling constant $\mathrm{J}_{\text {Lines }}$ since all the information about crystal field splitting and magnetic anisotropy are computed ab initio. $\mathrm{J}_{\mathrm{Heis}}$ have been successfully used as guess values for the $\mathrm{J}_{\text {Lines }}$.

## Single Ions' properties

Table S5. Values of the main magnetic axes of the ground Kramers' doublet for Dy and Co in $\left[\mathrm{Co}^{\mathrm{II}} \mathrm{Dy}{ }^{\text {III }}\left(R-\mathrm{L}^{4} \mathrm{H}\right)(\mathrm{hfac})_{5}\right](5 a)$, and their orientations in the crystal frame, mapped within the pseudospin approach.

The Dy ion shows a pronounced easy axis anisotropy, while the situation for $\operatorname{Co}(\mathrm{II})$ is intermediate between easy axis and easy plane. Indeed, if we go beyond the pseudospin approach, and we map the $\operatorname{Co}($ II $)$ anisotropy within the following zero field splitting hamiltonian,

$$
\mathrm{H}_{\mathrm{zfs}}=\mathrm{D} \cdot\left[\mathrm{~S}_{z}^{2}-\mathrm{S} \cdot \frac{\mathrm{~S}+1}{3}\right]+\mathrm{E} \cdot\left[\mathrm{~S}_{\mathrm{x}}^{2}-\mathrm{S}_{\mathrm{y}}^{2}\right]
$$

where the effective spin $S=3 / 2$ for $\mathrm{Co}(\mathrm{II})$ is employed, the obtained parameters are reported in Table S7. As we can observe, the value for E is near the limit of $\mathrm{D} / 3$, indicating a strong rhombic contribution, i.e. large deviation from axiality.

Table S7. Computed Zero Field Splitting (in $\mathrm{cm}^{-1}$ ) parameters for Co (II) ion in compound 5a.
